Hi Angus,

this cannot be done currently, but it is not the first time to here the request. I may consider...

A way would be (similar to automatic SAR) determining core fragments, e.g. Murcko, and then for all molecules with matching core fragments analyse changing substituents. Then create a result table with these columns:

- 1 - core fragment with R1,r2,... for every chaging substituent position
- 2 - substituent position (R1 or R2 or ...)
- 3 - Structure of substituent at this position
- 4 - mean contribution of this substituent at this position to activity
- 5 - count of this substituent found at this position
- 6 - StdDev of constribution value (this substituent at this position)

Is it this that you have in mind?

Thomas
