Hi Angus,

I admit that currently the handling of explicit variables is neither consistent not complete.
It is very new and was done as a (possibly to quick) solution for an internal problem.

You can refer to you variable in task 2 (formula for calculated values), if you put a '$' sign ahead of the name.
When solving the equation for every row, the expression calculator treats your variable input as a column name.
If such a column exists, the row's value of that column (and not your input value) is used when solving the equation.

I am not sure, whether this is already part of 4.7.2, it certainly is in 4.7.3, which is the current Windows download.

Thomas
