DataWarrior's model to assign Druglikeness depends on the encoded structure a tautomer is represented. With *Ambit-Tautomer*, Kochev et al. published an open source tool (Java based), to predict tautomers and to rank their likelihood.

If wanted, their executable may be run without the larger *Ambit* framework, just by

```
java -jar ambit-tautomers-2.0.0-SNAPSHOT.jar
```

Thus, I would like to suggest DataWarrior could implement a function to check if the structures to consider could reasonably yield a tautomer worth to probe equally. This equally could be complementary to your recently published reference *tautomer.dwar*.

Out of curiosity, I drew a pyridone, a pyrazole, and a thalomid with ACD ChemSketch in two tautomeric forms, exported the SMILES strings (as defined by ACD ChemSketch) into a *.smi* file:

With *openbabel*, it was converted into a *.sdf* accessible for DataWarrior by

```
obabel -ismi tautomers.smi -osd -O tautomers.sdf
```

successfully read and used to compute the Druglikeness. At least as the examples about «hydroxypyridine» and the enol form of the thalomid differ in the results examined.

To ease replication of the findings, the relevant files are provided below.

Publication about *Ambit-Tautomer*: <https://doi.org/10.1002/minf.201200133>

This is, of course, and important issue. Having the right tautomer to start with is crucial for any reliable prediction.

The intention behind the work on the published tautomer database is to allow others and ourselves to work on algorithms

to predict the most prominent tautomer. If we had such an algorithm with a reasonable performance at hand, we could use

it as input before training any prediction model. It also would allow to normalize pKa databases to improve or develop

algorithms to more reliably predict pKa-values, which is also in big demand. We have it in the pipeline, but it will

take time...
